

# PHIL3110 - Exam

Maxwell Bo

June 21, 2018

## Part A

### Problem 1

1. Let  $\beta = \{\varphi \mid \varphi \in \Gamma \wedge \varphi \in \Delta\}$ .

Say there's some  $\varphi$  such that  $\beta \models \varphi$  but  $\varphi \notin \beta$ . If  $\varphi \notin \beta$ , then  $\varphi \notin \Gamma$  and  $\varphi \notin \Delta$ .

ABORTATIVE I looked for a counter-example  $\varphi$  that could both be true in two separate sets, but when stripped of its environment (all the  $\psi$ s in which  $\psi \in \Gamma$  but  $\psi \notin \Delta$ , and vice-versa) allowed a derivation to something that was not in  $\Gamma$  and  $\Delta$ . I found this very difficult.

2. Let  $\Xi$  be  $\{\varphi\}$  such that for any  $\psi$  not equal to  $\varphi$ ,  $\varphi \not\models \psi$ . In other words,  $\varphi$  only derives itself.

$\Xi$  is a theory. By completeness,  $\Xi \models \varphi$ , and  $\varphi \in \Xi$ . Furthermore, also by completeness, there is no  $\psi$  such that  $\Xi \models \psi$  and  $\psi \notin \Xi$ .

Choose some arbitrary  $\chi$ . Let  $\Gamma = \Xi \cup \{\chi\} \cup \{\text{sentences required to make } \Gamma \text{ a theory}\}$ .

$\Xi$  is a proper subset of  $\Gamma$ .  $\Gamma$  is a theory. Yet  $\Xi$  is a theory. This serves as a counter-example.

### Problem 2

$$(P \rightarrow Q) \rightarrow P$$

### Problem 3

Let  $A$  be the range of the increasing total recursive function  $f : \omega \rightarrow \omega$ . We interpret “range” to mean the image of the function, not its co-domain.

Thus,

$$A = \text{im}(f) = \{f(a) \mid a \in \text{dom}(f)\}$$

Recalling DEFINITION 190<sup>1</sup> and DEFINITION 191<sup>2</sup>, we'll construct a function that for any  $n$  will verify whether or not it is in  $A$ , and halts in finite time.

We'll reason informally about this function.

First, we'll assume that  $\text{im}(f)$  is finite. As  $f$  is increasing, it is injective. As it is injective,  $\text{dom}(f)$  is finite. As  $f$  is a total recursive function, it halts in finite time for all inputs in its domain. Therefore, collecting all  $f(n)$  for every  $n \in \text{dom}(f)$  halts in finite time. Checking membership of a finite set halts in finite time. If  $a$  is in this set,  $a \in A$ , otherwise  $a \notin A$ .

Secondly, we'll assume that  $\text{im}(f)$  is infinite. For every  $n \in \text{dom}(f)$ , we compute  $f(n)$  (in finite time). If  $f(n) = a$ , we halt, and confirm that  $a \in A$ . If  $f(n) > a$ , we halt, and confirm that  $a \notin A$ . As  $f$  is increasing, we can assume that some successive  $n$  will never produce something that is equal to  $a$  - e.g. we are allowed to halt when  $f(n) > a$ . As  $a \in A$  describes some finite point in the ordered  $\omega$ , checking that  $a \in A$  will halt in finite time.

## Problem 4

Given:

- for  $x \in M$ ,  $x$  is regular  $\Leftrightarrow x \in R^{\mathcal{M}}$
- for  $x \in N$ ,  $x$  is perfect  $\Leftrightarrow x \in P^{\mathcal{N}}$
- Every derivation in  $M$  is regular
- Every derivation in  $N$  is perfect

We'll assume for both  $\mathcal{M}$  and  $\mathcal{N}$ , that for each constant symbol  $a$ ,  $a^{\mathcal{M}} = a$  and  $a^{\mathcal{N}} = a$

We can thus conclude that  $M = R^{\mathcal{M}}$  and  $N = P^{\mathcal{N}}$ .

We can say that  $\mathcal{M} \models \forall x R x$  and  $\mathcal{N} \models \forall x P x$ .

1.  $\mathcal{N}$  has a non-empty quantifiable domain,  $N$ . If  $\mathcal{N} \models \forall x P x$ , then  $\mathcal{N} \models \exists x P x$ . Therefore,  $\mathcal{N} \models \exists x P x$ .
2. Fix  $\mathcal{M}^+$  such that there is some new  $m \in \mathcal{L}(C)$ , such that  $m^{\mathcal{M}^+} = m$ , where  $m \notin P^{\mathcal{M}^+}$ .  $\mathcal{M}^+$  is a valid substitute for  $\mathcal{M}$ , as it can be constructed using the rules specified prior.

Thus,  $\mathcal{M} \not\models \forall x P x$ .

3. Note that  $\forall x R x$  is a  $\Pi_1$  sentence (a  $\forall$ -sentence). By THEOREM 139(2)<sup>3</sup>, if  $\varphi$  is  $\Pi_1$ , and  $N \subseteq M$ , and  $\mathcal{M} \models \varphi$ , then  $\mathcal{N} \models \varphi$ . As specified prior  $\mathcal{M} \models \forall x R x$ . Therefore  $\mathcal{N} \models \forall x R x$ .
4.  $\mathcal{N}$  has a non-empty quantifiable domain,  $N$ . If  $\mathcal{N} \models \forall x P x$ , then  $\mathcal{N} \models \exists x P x$ . For  $N \subseteq M$  to be true, if  $m \in P^{\mathcal{N}}$ , then  $m \in P^{\mathcal{M}}$ . Therefore  $m \in P^{\mathcal{M}}$ . Therefore  $\mathcal{M} \models \exists x P x$ .

## Problem 6

1. Let  $\mathcal{M}$  be a model with domain  $M = \{\}$ .

$\nexists x(x = x)$  is a consequence.

Furthermore, we run into some strangeness when we find that  $\forall x(x \neq x)$  is a consequence.

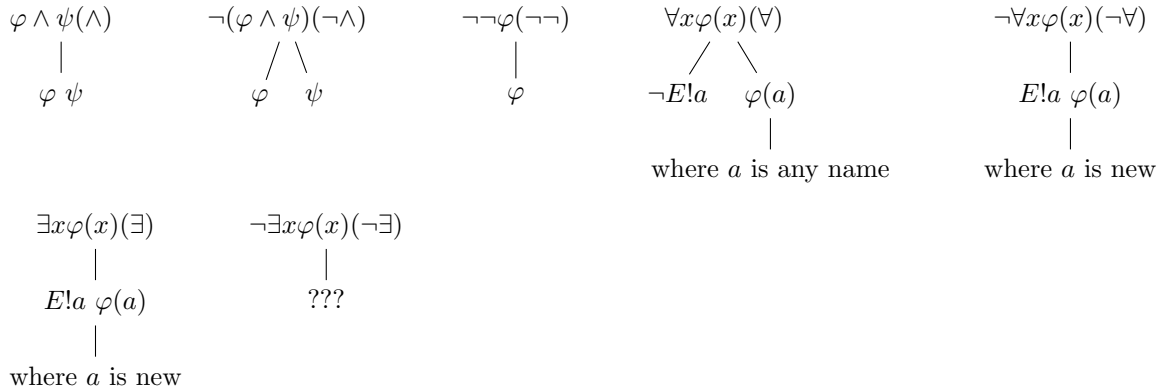

$\forall x \varphi(x) \Rightarrow \exists x \varphi(x)$  no longer holds either.

In other words, free logic admits existentially quantified formulas always being false in the empty domain, and universally quantified formulas always being true.

Furthermore, the notion that  $\neg \exists x \varphi(x) \Rightarrow \forall x \neg \varphi(x)$  ceases to be meaningful.

### 2. Rules

We're also going to consider  $\exists$  in the set logical vocabulary, because, why not?

---

<sup>3</sup>Page 85 of course notes

where  $E!c$  expands to  $\exists x(x = c)$ <sup>4</sup>.

By new we mean that the name  $a$  has not occurred anywhere on the branches above.

3. Our goal is to show that if  $\models_f \varphi$ , then  $\vdash_{Tab} \varphi$ . In other words, if every model  $\mathcal{M}$  (of the language  $\varphi$ ) is such that if  $\mathcal{M} \models \varphi$  then the tableau commencing with  $\neg\varphi$  is closed.

By contraposition, if  $\not\vdash_{Tab} \varphi$  then  $\not\models_f \varphi$ .

In other words, if the tableau commencing with  $\neg\varphi$  does not close, then there is some  $\mathcal{M}$  such that  $\mathcal{M} \models \neg\varphi$ .

Rather than choosing some open branch  $\mathcal{B}$  of a tableau commencing with  $\neg\varphi$ , and defining a  $\mathcal{M}^{\mathcal{B}}$ , and reasoning with  $+$ -complexity, we'll use a  $\Delta$  that is maximally consistent<sup>5</sup> and existentially witnessed<sup>6</sup> set of sentences.

Let  $\mathcal{M}^\Delta$  be such that:

- $M^\Delta$  is the set of constant symbols  $a$  occurring in the sentences in  $\Delta$ .
- for each constant symbol  $a$ , let  $a^{\mathcal{M}} = a$
- for each  $n$ -ary relation symbol  $R$  of  $\mathcal{L}(C)$  let  $R^{\mathcal{M}}$  be the set of  $n$ -tuples  $\langle a_1, \dots, a_n \rangle$  such that  $Ra_1, \dots, a_n$  is in  $\Delta$ .

Reiterating

**Claim 120** *Suppose  $\Delta$  is maximal consistent. Then  $\varphi \in \Delta \Leftrightarrow \mathcal{M}^\Delta \models \varphi$*

but eliding PROOF 120<sup>7</sup>.

We will show  $\varphi \in \Delta \Rightarrow \mathcal{M}^\Delta \models \varphi$

We proceed by induction on the complexity of the formula.

### Base

Suppose  $\psi := \chi$ . Then

$$\chi \in \Delta \Leftrightarrow \mathcal{M}^\Delta \models \chi$$

This flows trivially from CLAIM 120.

### Induction Step

- Suppose  $\psi := \chi \wedge \delta \in \Delta$ .

We claim that  $\chi \wedge \delta \in \Delta$  iff both  $\chi \in \Delta$  and  $\delta \in \Delta$ .

If  $\chi \wedge \delta \in \Delta$ , then by Claim 120 and tableau rule  $(\wedge)$ , we have both  $\chi$  and  $\delta$  in  $\Delta$ .

$$\begin{aligned} \chi \wedge \delta \in \Delta &\Rightarrow \chi \in \Delta \text{ and } \delta \in \Delta \\ &\Leftrightarrow \mathcal{M}^\Delta \models \chi \text{ and } \mathcal{M}^\Delta \models \delta \\ &\Leftrightarrow \mathcal{M}^\Delta \models \chi \wedge \delta \end{aligned}$$

The first  $\Rightarrow$  is via our claim; the second  $\Leftrightarrow$  is by induction hypothesis; and the last  $\Leftrightarrow$  is from the  $\models$  definition.

<sup>4</sup>I had to do this because the forest package wouldn't typeset leaves over a certain number of characters

<sup>5</sup>for an arbitrary  $\varphi$  either  $\varphi \in \Delta$  or  $\neg\varphi \in \Delta$

<sup>6</sup>if  $\exists x\varphi(x) \in \Delta$ , then for some constant symbol  $a$ ,  $\varphi(a) \in \Delta$

<sup>7</sup>Page 77 of course notes

- Suppose  $\psi := \neg\chi$ .  
If  $\chi \in \delta$ , then by CLAIM 120 and tableau rule ( $\neg$ ),  $\chi \notin \Delta$ .

$$\begin{aligned}\neg\chi \in \Delta &\Leftrightarrow \chi \notin \Delta \\ &\Leftrightarrow \mathcal{M}^\Delta \not\models \chi \\ &\Leftrightarrow \mathcal{M}^\Delta \models \neg\chi\end{aligned}$$

The first  $\Leftrightarrow$  is via the completeness of  $\Delta$ ; the second  $\Leftrightarrow$  is by the induction hypothesis; and the last is via the  $\models$  definition.

- Suppose  $\psi := \forall x\chi(x)$ .  
We claim  $\forall x\chi(x) \in \Delta$  for every constant symbol  $a \in \mathcal{L}(C)$  such that  $\chi(a) \in \Delta$ .  
Suppose  $\forall x\chi(x) \in \Delta$ .  
Suppose  $\mathcal{L}(C) \neq \{\}$ , which given our definition of  $\mathcal{M}^\Delta$ , occurs when  $M^\Delta \neq \{\}$ .  
Then by claim CLAIM 120 and tableau rule ( $\forall$ ), for all  $a \in \mathcal{L}(C)$ ,  $\chi(a) \in \Delta$ .  
Suppose  $\mathcal{L}(C) = \{\}$ . We assert that there must be something in  $\Delta$  that says there is no  $a \in \mathcal{L}(C)$ .  
Then by CLAIM 120 and tableau rule ( $\forall$ ), there is some  $\varphi$  of the form  $\neg\exists y(y = a)$  such that  $\varphi \in \Delta$ .  
On the other hand, if for some some  $a \in \mathcal{L}(C)$ ,  $\chi(a) \in \Delta$ , then by CLAIM 120 and ( $\forall$ ),  $\forall x\chi(x) \in \Delta$ .  
Then we have

$$\begin{aligned}\forall x\chi(x) \in \Delta &\Rightarrow \text{for all } a \in M^\Delta, \chi(a) \in \Delta \text{ or } \neg\exists y(y = a) \in \Delta \\ &\Leftrightarrow \text{for all } a \in M^\Delta, \mathcal{M}^\Delta \models \chi(a) \in \Delta \text{ or } \mathcal{M}^\Delta \models \neg\exists y(y = a) \\ &\Leftrightarrow \mathcal{M}^\Delta \models \forall x\chi(x)\end{aligned}$$

The first  $\Rightarrow$  is via our claim; the second  $\Leftrightarrow$  is by induction hypothesis; and the final  $\Leftrightarrow$  is via the  $\models$  definition.

- Suppose  $\psi := \exists x\chi(x)$ .  
Then we claim  $\exists x\chi(x) \in \Delta$  iff there is some constant symbol  $a \in \mathcal{L}(C)$  such that  $\chi(a) \in \Delta$ .  
Suppose  $\exists x\chi(x) \in \Delta$ .  
By the construction of  $\Delta^8$ , CLAIM 120 and tableau rule ( $\exists$ ), there is some  $a \in \mathcal{L}(C)$  such that  $\chi(a) \in \Delta$ .  
Furthermore we may also say that there exists some  $\varphi$  of the form  $\exists y(y = a)$ , such that  $\varphi \in \Delta$ .  
We would not be able to say this if  $\Delta$  were not existentially witnessed.  
Then we have

$$\begin{aligned}\exists x\chi(x) \in \Delta &\Leftrightarrow \text{there is some } a \in M^\Delta \text{ such that } \chi(a) \in \Delta \text{ and } \exists y(y = a) \in \Delta \\ &\Leftrightarrow \text{there is some } a \in M^\Delta \text{ such that } \mathcal{M}^\Delta \models \chi(a) \text{ and } \mathcal{M}^\Delta \models \exists y(y = a) \\ &\Leftrightarrow \mathcal{M}^\Delta \models \exists x\chi(x)\end{aligned}$$

The first  $\Rightarrow$  is via our claim; the second  $\Leftrightarrow$  is by induction hypothesis; and the final  $\Leftrightarrow$  is via the  $\models$  definition.

The other cases are left as exercises for the marker.
